

## Homework-07 Due Tue Nov.-22, 2005

- Show that the solutions to the (nonlinear) geostrophic adjustment problem

$$\begin{aligned} h(x) &= H [1 - \exp(x-L_D)/L_D)] \\ v(x) &= -(g'H)^{1/2} \exp(x-L_D)/L_D) \end{aligned}$$

are consistent with the thermal wind equation

$$\partial_z v = -g/(\rho_0 f) \partial_x \rho$$

which writes in discrete form (Margules relation)

$$\Delta v/\Delta z = -g/(\rho_0 f) \Delta \rho/\Delta x$$

where the variable  $h$  is the thickness of the upper layer of density  $\rho$  overlaying a lower layer of density  $\rho_0$ ,  $v$  is the along-front velocity,  $L_D = (g'H)^{1/2}/f$  is the internal Rossby radius of deformation, and  $g' = g\Delta\rho/\rho_0$  is the reduced gravity [10 pts].

- Please find and correct ALL errors in the statement:

“...the thermal wind relation  $\partial_z u = g/(\rho_0 f) \partial_x \rho$  gives the horizontal velocity shear as a function of depth. A reference velocity is not necessary to estimate this quantity, however, one must prescribe a vanishing pressure gradient at the bottom to estimate a geostrophic velocity in a continuously stratified fluid...” [5pts]

- Below you find a graphical presentation of the density anomaly  $\rho - 1000 \text{ kg/m}^3$  (contours) and temperature (colors) fields taken during a survey Sept. 22-26, 2004 near 73N latitude in the Arctic Ocean (courtesy of Dr. Pickart, WHOI, see [http://www.whoi.edu/arcticedge/arctic\\_west04/update/](http://www.whoi.edu/arcticedge/arctic_west04/update/) for a narrative). Use the thermal wind relation to roughly estimate the geostrophic velocity field associated with this feature assuming that the horizontal pressure gradient vanishes at 300-m depth. More specifically, estimate currents relative to no flow at 300-m at distances (5,15,25) km and depths (50,100,150,250) m and sketch the results. What is the Rossby number (relative to planetary vorticity) of this feature. [10 pts]
